Geomatic Research Center, Laval University  
Canadian Center for Remote Sensing, Ottawa

Image Segmentation  
is the division of  
the image plane  
into regions

Two basic questions:

- 1- **What** kind of regions do we want ?
  - Homogeneous regions
  - Segment similarity
- 2- **How** can we obtain them ?
  - Algorithm desing

# HIERARCHICAL SEGMENTATION BY STEP-WISE OPTIMISATION

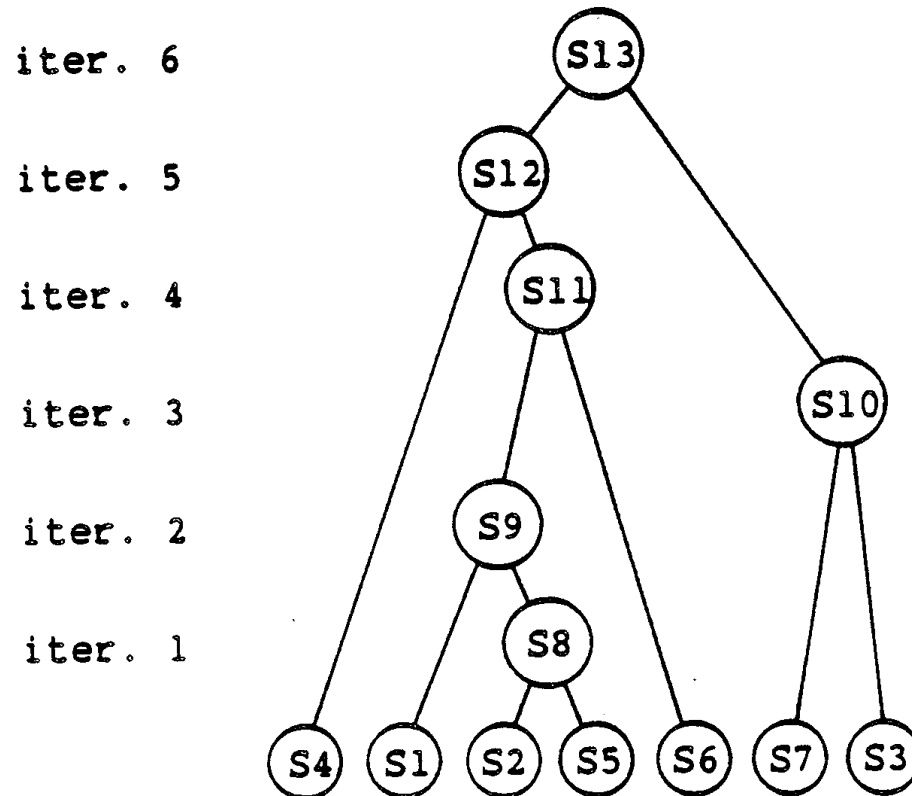

A hierarchical segmentation begins with an initial partition  $P^0$  (with  $N$  segments) and then sequentially merges these segments.

## STEP-WISE OPTIMISATION

- A criterion, corresponding to a measure of segment similarity, is used to define which segments to merge.
- At each iteration, an optimization process finds the two most similar segments and merges them.
- This can be represented by a segment tree, one node per iteration, where only the two most similar segments are merged.

## Sequence of segment merges.

## Implantation aspects

- too many segments
- merge only neighbour segments
- avoid recalculation

# IMAGE APPROXIMATION

- Each segment,  $S_i$ , is represented by an approximation function,  $r_i(x,y)$ .
- The approximation error is defined as

$$H(S_i) = \sum_{(x,y) \in S_i} (f(x,y) - r_i(x,y))^2$$

- The goal is to find the image segmentation that produces the lowest overall approximation error.
- In hierarchical segmentation, this results in sequentially merging the segments that produce the smallest increases in the approximation error.
- Thus, the step-wise criterion is

$$C_{i,j} = H( S_i \cup S_j ) - H( S_i ) - H( S_j )$$

- This assures that each iteration does its best to minimize the overall approximation error.

## Constant value approximation

$$f_i(x, y) \simeq r_i(x, y) = \mu_i \quad (\text{mean})$$

$$C_{i,j} = \frac{N_i \times N_j}{N_i + N_j} [\mu_i - \mu_j]^2$$

Multi-spectral image

$$C_{i,j} = \frac{N_i \times N_j}{N_i + N_j} \sum_k w^k [\mu_i^k - \mu_j^k]^2$$

# A SMALL EXAMPLE

# SHAPE CRITERIA

- Bonding box – perimeter Cp
- Bonding box – area Ca
- Contour length Cl

New criteria

$$C_{s_{i,j}} = C_{i,j} * Cp^2 * Ca * Cl$$

## Bonding box – perimeter

$$C_p = \frac{\text{perimeter of } S_i \cup S_j}{\text{perimeter of bonding box}}$$

## Bonding box – area

$$Ca = \frac{\text{area of bonding box}}{\text{area of } S_i \cup S_j}$$

## Contour length

$L_c$  = length of common part of contours

$Lex\ i$  = length of exclusive part for  $S_i$

$$Cl = \text{Min} \left\{ \frac{Lex\ i}{L_c}, \frac{Lex\ j}{L_c} \right\}$$

# CONCLUSION

- Hierarchical segmentation produces good results
- Criterion should be adapted to the application
- The first merges should be done correctly
- Shape criteria are useful
